

METHOD FOR THE TREATMENT OF INFLAMMATORY DISORDERS
RELATED APPLICATIONS

This is a continuation of PCT/US00/15004, filed on June 1, 2000, which claims priority from U.S. provisional application Serial No. 60/185,336 filed on February 29, 2000 and
5 U.S. provisional application Serial No. 60/137,038 filed on June 01, 1999.

BACKGROUND OF THE INVENTION

Integrins are cell surface protein complexes that form a large class of cell-surface molecules mediating adhesion of cells to each other and their surrounding. Cells need to adhere to each other and to other molecules in their environment in many developmental
10 and physiological processes. Examples include the creation of tissues and organs and the maintenance of their integrity. Including amongst these physiological processes are inflammatory disorders.

One of the key steps during the inflammatory process involves the extravasation of cells out of the blood vessels, into the tissues, and towards the site of infection. The role of
15 adhesion molecules in this process is often broken down into a three step model involving initial leukocyte 'rolling' on inflamed endothelium, followed by firm attachment, and resulting in transendothelial migration of leukocytes into the inflamed tissues (Hynes, R.O. 1992 *Cell* 69:11-25; Springer, T.A. 1992 *Cell* 76:301-314). A further critical step in the inflammatory cascade, and one that has not been extensively explored, occurs within
20 the peripheral tissues where infiltrating, as well as resident cells, need to migrate towards the site of infection, recognize foreign antigen, and undergo cellular activation in order to perform their effector functions. To directly assess the importance in inflammation of interstitial adhesive interactions in isolation from the role adhesive interactions play in leukocyte recruitment, we have focused on the importance of adhesion molecules of the
25 integrin family and fragments thereof, and their role in animal models of inflammation, particularly arthritis.

SUMMARY OF THE INVENTION

The present invention provides a method for treatment of inflammatory disorders in a subject. Specifically, the invention provides a method for treatment of arthritis.

More particularly, the invention provides a method for the treatment of an inflammatory disorder in a subject comprising administering to the subject a pharmaceutical composition comprising an effective amount of an $\alpha 1\beta 1$ function blocking antibody or a fragment of the antibody, wherein the $\alpha 1\beta 1$ function blocking antibody or fragment is capable of binding an epitope of VLA-1 comprising amino acid residues 92-97, Val-Gln-Arg-Gly-Gly-Arg.

The anti-integrin antibody can be selected from the group consisting of a human antibody, a chimeric antibody, a humanized antibody and fragments thereof. The anti-integrin antibody can be a monoclonal or polyclonal antibody.

The invention further provides a method for treating inflammatory disorders in a subject that is a human or animal subject.

All of the cited literature in the preceding section, as well as the cited literature included in the following disclosure, are hereby incorporated by reference.

DESCRIPTION OF THE DRAWINGS

Figure 1. *Collagen-binding integrins $\alpha 1\beta 1$ and $\alpha 2\beta 1$ on activated leukocytes.*

(A). Flow cytometric analysis of $\alpha 1$ and $\alpha 2\beta 1$ integrin expression on IL-2-activated splenocytes (d 11). Cells were labeled with either anti- $\alpha 1$ mAb, anti- $\alpha 2$ mAb, or non-binding control mAb (grey lines), and followed by FITC-anti-hamster immunoglobulin. (B) Effect of anti- $\alpha 1$ and anti- $\alpha 2$ mAbs on leukocyte adhesion to collagen. 10^5 IL-2 activated splenocytes were treated with indicated mAbs for 15 min before plating onto either type IV or type I collagen-coated wells for 1 h at 37°C. Adhesion was calculated as illustrated in Example 1, and expressed as % adhesion relative to control mAb-treated cells. Adhesion assays were done in triplicate, and at least three independent experiments were performed. One representative experiment is shown.

Figure 2. *Effect of anti-integrin mAbs on the effector phase of delayed-type hypersensitivity.* SRBC-sensitized mice were injected i.p. with the indicated mAbs 1 h prior to SRBC challenge. Footpad thickness was measured 20 h after antigen challenge, and results shown as % increase in footpad thickness \pm SEM as illustrated in Example 2. These data represent a summary of eight experiments with n = 79 (PBS), 68 (control hamster Ig), 68 (anti- $\alpha 1$), 29 (anti- $\alpha 2$), 18 (anti- $\alpha 1$ + anti- $\alpha 2$), 45 (anti- $\alpha 4$), 18 (anti- $\alpha 5$),

20 (anti- $\alpha 6$), and 10 (anti- $\beta 1$). The mAbs used were: Ha4/8 (control hamster Ig group 2), Ha31/8 (anti- $\alpha 1$), Ha1/29 (anti- $\alpha 2$), PS/2 (anti- $\alpha 4$), 5H10-27 (anti- $\alpha 5$), GoH3 (anti- $\alpha 6$), and HM β 1-1 (anti- $\beta 1$).

Figure 3. *Effect of anti-integrin mAbs on the effector phase of contact*

5 *hypersensitivity.* FITC-sensitized mice were injected i.p. with the indicated mAbs 4 h prior to FITC challenge. Ear thickness was measured at baseline and 24 h later, and results shown as % increase in ear thickness \pm SEM as illustrated in Example 3. These data represent a summary of nine experiments with n = 74 (PBS), 60 (control hamster Ig), 26 (anti-ICAM-1), 44 (anti- $\alpha 1$), 44 (anti- $\alpha 2$), 38 (anti- $\alpha 1$ + anti- $\alpha 2$), 36 (anti- $\alpha 4$), 16 (anti-
10 $\alpha 5$), 26 (anti- $\alpha 4$ + anti- $\alpha 5$), 24 (anti- $\alpha 6$), and 22 (anti- $\beta 1$). The hamster mAbs used were: Ha4/8 (control hamster Ig group 2), Ha31/8 (anti- $\alpha 1$), Ha1/29 (anti- $\alpha 2$), HM β 1-1 (anti- $\beta 1$), 3E2 (anti-ICAM-1); the rat mAbs used were: R35-95 and R35-38 (control rat IgG2a and rat IgG2b, respectively), PS/2 (anti- $\alpha 4$), 5H10-27 (anti- $\alpha 5$), GoH3 (anti- $\alpha 6$).

Figure 4. *Contact hypersensitivity responses in $\alpha 1$ -deficient mice compared to*

15 *wild-type mice.* FITC-sensitized mice were injected i.p. with indicated mAbs 4 h prior to FITC challenge. Ear thickness was measured at baseline and 24 h later, and results shown as % increase in ear thickness \pm SEM as illustrated in Example 4. Groups of four to five mice per condition were used, and all experiments were performed a minimum of three times. One representative experiment is shown.

Figure 5. *Effect of anti- $\alpha 1$ and anti- $\alpha 2$ mAbs on croton oil-induced non-specific*

20 *inflammation.* Mice were injected i.p. with indicated mAbs 4 h prior to ear painting with croton oil. Ear thickness was measured at baseline and 24 h later, and results shown as % increase in ear thickness \pm SEM as illustrated in Example 5. Groups of four to five mice per condition were used, and all experiments were performed a minimum of three times.
25 One representative experiment is shown.

Figure 6. *Effect of anti- $\alpha 1$ and $\alpha 2$ mAbs in collagen mAb-induced arthritis.* Mice

were injected i.p. with anti-collagen mAbs at d 0, followed by LPS on day 3. Mice were injected i.p. with indicated mAbs every 3rd day starting on d 0. Clinical arthritis was apparent 2-3 d following LPS injection and continued for several weeks. Each limb was
30 evaluated on a 0 to 4 scale every 3rd day as illustrated in Example 6 and results are

expressed as the mean arthritic score between d 9 and d 15 (\pm SEM) of all four limbs. These data represent a summary of four experiments with each experiment consisting of groups of three to four mice per condition.

Figure 7. Administration of anti- α 1 or anti- α 2 mAbs inhibits leukocyte

5 infiltration into footpads during a DTH response. The experiment was performed as described in Figure 2. Footpads were excised 20 h following antigen challenge and tissue sections stained with hematoxylin and eosin. Tissue sections are from footpads of either unchallenged mice (A) or SRBC-sensitized mice challenged with SRBC (B-H). Mice were treated 1 h prior to challenge with either PBS (B), control hamster Ig (C, G), anti- α 1 (D),
10 anti- α 2 (E) or a combination of anti- α 1 and anti- α 2 mAbs (F, H). Magnification: x 100 (A-F), x 400 (G-H).

Figure 8. α 1 β 1 is expressed on infiltrating leukocytes in footpads during a DTH response. Immunohistochemical staining of infiltrating leukocytes from an untreated inflamed footpad 20 h after antigen challenge. (A). Serial sections stained directly with
15 Alexa488-conjugated control mAb and anti- α 1 mAb. (B). Dual immunofluorescent staining with Alexa488-conjugated anti- α 1 mAb and Phycoerythrin (PE)-conjugated cell lineage-specific mAbs. PE-conjugated mAbs utilized were specific for granulocytes/monocytes (anti-CD11b), neutrophils (anti-Ly6G/Gr-1), and T lymphocytes (anti-CD3). Magnification: x 400.

20 **Figure 9.** Effect of anti- α 1 and α 2 mAbs in collagen mAb-induced arthritis. (A). Preventative treatment of mice with either anti- α 1 or anti- α 2 mAb decreases arthritic score. Mice were treated with anti-collagen mAbs at d 0, followed by LPS on d 3. Arthritis was apparent by d 6 and continued for several weeks. Mice were treated with the indicated mAbs every 3rd day starting on d 0. Each limb was evaluated and scored on a 0
25 to 4 scale every 3rd day. Results are expressed as the mean arthritic score between d 9 and d 15 (\pm SEM) of all four limbs (maximum score of 16). Groups of 4 mice per condition were used; the average of 12 experiments is shown. (B). α 1-deficient mice have a reduced arthritic score comparable to anti- α 1 mAb-treated wild-type mice. Experimental details and scoring are as outlined above. Groups of 4 mice per condition were used; the
30 average of 2 experiments is shown.

Figure 10. Effect of anti- $\alpha 1$ mAb treatment on the immunopathology of arthritic joints. Anti- $\alpha 1$ mAb treatment reduces leukocytic infiltration, adherence of cells to joint surfaces, and cartilage destruction as evidenced by proteoglycan loss. Hind limbs from normal mice (A-D) or arthritic mice (d 8) receiving either control hamster Ig (E-H) or anti- $\alpha 1$ mAb treatment. (I-L). Limbs were photographed (A, E, I), excised, and tissue sections stained either with hematoxylin/eosin (B-C, F-G, J-K) or with toluidine blue to detect proteoglycan (D, H, L). Magnification: x 16 (B, F, J); x 160 (C, G, K); x 200 (D, H, L).

Figure 11. Development of arthritis is delayed in the absence of lymphocytes and inhibition of arthritis by anti- $\alpha 1$ mAb occurs in the absence of lymphocytes. Wild-type B6,129 or RAG-1-deficient B6,129 mice were treated with anti-collagen mAbs at day 0, followed by LPS on day 3. Arthritis was apparent by day 6 and continued for several weeks. Mice were treated with the indicated mAbs every 3rd day starting on day 0. Each limb was evaluated and scored on a 0 to 4 scale every 3rd day. Results are expressed as the mean arthritic score per limb (maximum score of 4). Groups of 4 mice per condition were used.

Figure 12. Dose response of anti- $\alpha 1$ mAb inhibition of arthritis. Wild-type Balb/c mice were treated with anti-collagen mAbs at day 0, followed by LPS on day 3. Arthritis was apparent by day 6 and continued for several weeks. Mice were treated i.p. with the indicated dose of either Ha4/8 (isotype control) or Ha31/8 (anti- $\alpha 1$) mAbs every 3rd day starting on day 0. Each limb was evaluated and scored on a 0 to 4 scale every 3rd day. Results are expressed as the mean arthritic score per limb (maximum score of 4). Groups of 4 mice per condition were used.

Figure 13. Therapeutic treatment with anti- $\alpha 1$ mAb can decrease arthritic score. Wild-type Balb/c mice were treated with anti-collagen mAbs at day 0, followed by LPS on day 3. Arthritis was apparent by day 6 and continued for several weeks. Mice were treated i.p. with mAbs (250 ug) or Ig fusion protein (200 ug) every 3rd day starting on day 4. Mice received either mAb (Ha4/8 isotype control or Ha31/8 anti- $\alpha 1$), Ig fusion protein (Isotype control Ig or TNF-R55-Ig) or a combination of both (250 ug Ha31/8 and 200 ug TNF-R55-Ig). Each limb was evaluated and scored on a 0 to 4 scale every 3rd day. Results

are expressed as the mean arthritic score per limb (maximum score of 4). Groups of 4 mice per condition were used.

Figure 14. *Location of the Epitope for the anti- $\alpha 1$ I domain Blocking mAbs.* A. Amino acid sequence of the rat (top) and human (below) $\alpha 1$ -I domain. The residues that comprise the MIDAS (metal ion dependent adhesion site) motif are shown in bold. The human amino acids that replaced the corresponding rat residues (RAH) are shown below the rat sequence in the boxed region. For clarity, residue numbering in the text refers to this figure. B. Increasing concentrations of mAb AJH10 were bound to plates coated with 30 $\mu\text{g}/\text{ml}$ human (circles), rat (triangles) or RAH (squares) $\alpha 1$ -I domain. Data shown is representative of three experiments.

Figure 15. Amino acid sequence of the human $\alpha 1$ -I domain.

Figure 16. *Identification of a blocking mAb to the $\alpha 1$ -I domain.* A. Increasing concentration of mAbs AEF3 (triangles) or AJH10 (circles) were bound to plates coated with 30 $\mu\text{g}/\text{ml}$ $\alpha 1$ -I domain. B. The $\alpha 1$ -I domain was treated with increasing concentrations of mAb AJH10 (diamonds) or mAb BGC5 (squares) and bound collagen IV (2 $\mu\text{g}/\text{ml}$) coated plates. C. K562- $\alpha 1$ cell were treated with increasing concentration of mAbs AEF3 (triangles) or AJH10 (circles) and bound to collagen IV (5 $\mu\text{g}/\text{ml}$) coated plates. 45-50% of cells added to each well adhered to collagen IV. Data shown is representative of three independent experiments.

Figure 17. *Species Cross-reactivity of the blocking mAbs.* A. Detergents lysates from (1) sheep vascular smooth muscle, (2) human leukemia K562- $\alpha 1$ cells or (3) purified RAH GST-I domain; (4) Rat GST- $\alpha 1$ I domain; and (5) human GST- $\alpha 1$ I domain were separated by 10-20% SDS-PAGE under non-reducing conditions, and immunoblotted with function-blocking mAb AJH10. Molecular weight markers are shown on the left; non-reduced $\alpha 1\beta 1$ integrin migrates at ~ 180 kDa; GST-I domain migrates at ~ 45 kDa. B. Rabbit vascular smooth muscle cells were incubated with either mAb AJH10 (bottom) or murine IgG control (top) and analyzed by fluorescence activated cell sorter (FACS).

Figure 18. *The $\alpha 1$ -I domain binds collagen.* A. Increasing concentrations of the human $\alpha 1$ -I domain were bound to plates previously coated with 1 $\mu\text{g}/\text{ml}$ collagen I (squares) or collagen IV (circles). Values shown have been corrected for background

binding to BSA. B. 2 $\mu\text{g/ml}$ human $\alpha 1$ -I domain was mixed with increasing concentration of an anti- human $\alpha 1$ integrin antibody 5E8D9 (squares) or an anti- human $\alpha 2$ - integrin antibody A2IIE10 (circles), and then bound to plates previously coated with 1 $\mu\text{g/ml}$ collagen IV. C. Plates were coated with 1 $\mu\text{g/ml}$ collagen IV or 3% BSA. $\alpha 1$ -I domain (2 $\mu\text{g/ml}$) was subsequently bound to coated plates plates in the presence of 1 mM Mn^{2+} , 1 mM Mg^{2+} , or 5 mM EDTA. Data shown is representative of three independent experiments.

DETAILED DESCRIPTION OF THE INVENTION

It is a discovery of the present invention that an antibody to an integrin and fragment thereof, particularly, an $\alpha 1$ -integrin subunit, can block the interaction of pro-inflammatory leukocytes with components of the extracellular matrix including, but not limited to collagens, laminin and fibronectin. While not intending to limit the invention to any single mechanism of action it is proposed that disruption of the interaction between the integrin and fragment thereof and the surrounding matrix may decrease the expression of pro-inflammatory cytokines. It is further proposed that antibodies to integrins and fragments thereof may be modulating the effector phases of inflammatory responses by acting at the level of the antigen-specific T cell. In addition, it is proposed that antibodies to integrins and fragments thereof may act by disrupting cell migration within tissues and/or effects on cellular priming and activation within tissues.

This discovery illustrates the importance of adhesion molecules of the integrin family, particularly $\alpha 1\beta 1$, in the peripheral tissue environment during conditions related to inflammation. It also extends the role of integrins family and fragments thereof in inflammation beyond leukocyte attachment and extravasation at the endothelial interface by highlighting the importance of the matrix-rich peripheral tissue environment to immune responses and it reveals peripheral tissues as a new point of intervention for adhesion based therapies.

The methods of the present invention contemplate the use of antibodies to integrins where the integrins contemplated include molecules which comprise a β chain, including but not limited to $\beta 1$, $\beta 2$, $\beta 3$, $\beta 4$, $\beta 5$, $\beta 6$, $\beta 7$, $\beta 8$, non-covalently bound to an α chain, including but not limited to $\alpha 1$, $\alpha 2$, $\alpha 3$, $\alpha 4$, $\alpha 5$, $\alpha 6$, $\alpha 7$, $\alpha 8$, $\alpha 9$, $\alpha 10$, αV , αL , αM , αX ,

α D, α E, α I**b**. Examples of the various integrins contemplated for use in the invention include, but are not limited to:

α 1 β 1, α 2 β 1, α 3 β 1, α 4 β 1, α 5 β 1, α 6 β 1, α 7 β 1, α 8 β 1, α 9 β 1, α 10 β 1,
 α V β 1, α L β 1, α M β 1, α X β 1, α D β 1, α I**b** β 1, α E β 1;

α 1 β 2, α 2 β 2, α 3 β 2, α 4 β 2, α 5 β 2, α 6 β 2, α 7 β 2, α 8 β 2, α 9 β 2, α 10 β 2,
 α V β 2, α L β 2, α M β 2, α X β 2, α D β 2, α I**b** β 2, α E β 2;

α 1 β 3, α 2 β 3, α 3 β 3, α 4 β 3, α 5 β 3, α 6 β 3, α 7 β 3, α 8 β 3, α 9 β 3, α 10 β 3,
 α V β 3, α L β 3, α M β 3, α X β 3, α D β 3, α I**b** β 3, α E β 3;

α 1 β 4, α 2 β 4, α 3 β 4, α 4 β 4, α 5 β 4, α 6 β 4, α 7 β 4, α 8 β 4, α 9 β 4, α 10 β 4,
 α V β 4, α L β 4, α M β 4, α X β 4, α D β 4, α I**b** β 4, α E β 4;

α 1 β 5, α 2 β 5, α 3 β 5, α 4 β 5, α 5 β 5, α 6 β 5, α 7 β 5, α 8 β 5, α 9 β 5, α 10 β 5,
 α V β 5, α L β 5, α M β 5, α X β 5, α D β 5, α I**b** β 5, α E β 5;

α 1 β 6, α 2 β 6, α 3 β 6, α 4 β 6, α 5 β 6, α 6 β 6, α 7 β 6, α 8 β 6, α 9 β 6, α 10 β 6,
 α V β 6, α L β 6, α M β 6, α X β 6, α D β 6, α I**b** β 6, α E β 6;

α 1 β 7, α 2 β 7, α 3 β 7, α 4 β 7, α 5 β 7, α 6 β 7, α 7 β 7, α 8 β 7, α 9 β 7, α 10 β 7,
 α V β 7, α L β 7, α M β 7, α X β 7, α D β 7, α I**b** β 7, α E β 7;

α 1 β 8, α 2 β 8, α 3 β 8, α 4 β 8, α 5 β 8, α 6 β 8, α 7 β 8, α 8 β 8, α 9 β 8, α 10 β 8,
 α V β 8, α L β 8, α M β 8, α X β 8, α D β 8, α I**b** β 8, α E β 8;

The methods of the present invention also contemplate the use of antibodies to integrin fragments including for example antibodies to a β chain alone, including but not

limited to $\beta 1$, $\beta 2$, $\beta 3$, $\beta 4$, $\beta 5$, $\beta 6$, $\beta 7$, $\beta 8$, as well as an α chain alone, including but not limited to $\alpha 1$, $\alpha 2$, $\alpha 3$, $\alpha 4$, $\alpha 5$, $\alpha 6$, $\alpha 7$, $\alpha 8$, $\alpha 9$, $\alpha 10$, αV , αL , αM , αX , αD , αE , $\alpha IIIb$. In addition, the methods of the present invention further contemplate the use of antibodies to integrin fragments including for example antibodies to the I domain of the α chain,

5 including but not limited to the I domain from $\alpha 1\beta 1$ (Briesewitz et al., 1993 J. Biol. Chem. 268:2989); $\alpha 2\beta 1$ (Takada and Hemler, 1989 J Cell Biol 109:397), $\alpha L\beta 2$ (Larson et al., 1989 J Cell Biol 108:703), $\alpha M\beta 2$ (Corbi et al., 1988 J Biol Chem 263:12403), $\alpha X\beta 2$ (Corbi et al., 1987 EMBO J 6:4023), $\alpha D\beta 2$ (Grayson et al., 1988 J Exp Med 188:2187), $\alpha E\beta 7$ (Shaw et al., 1994 J Biol Chem 269:6016). In a preferred embodiment, 10 the $\alpha 1$ -I domain antigenic determinant comprises an amino acid sequence of at least 6 contiguous amino acids, wherein the contiguous sequence is found within the sequence of Figure 15. Moreover, in a preferred embodiment, the contiguous sequence is Val-Gln-Arg-Gly-Gly-Arg.

Methods for producing integrins for use in the present invention are known to those 15 of skill in the art (see for e.g. Springer et al. 1990, *Nature* 346:425-434).

Embodiments of the present invention further include anti-integrin polyclonal and monoclonal antibodies. Preferred embodiments of the present invention include a monoclonal antibody such an anti- $\alpha 1$ monoclonal antibody.

An $\alpha 1\beta 1$ function blocking antibody as used herein refers to an antibody that binds 20 to the $\alpha 1$ -I domain, specifically, residues 92-97 of Figure 15, and blocks $\alpha 1\beta 1$ function as tested for, example, by their ability to inhibit K562- $\alpha 1$ dependent adhesion to Collagen IV (see Example 15).

Preferred antibodies and homologs for treatment, in particular for human treatment, include human antibody homologs, humanized antibody homologs, chimeric antibody 25 homologs, Fab, Fab', F(ab')₂ and F(v) antibody fragments, and monomers or dimers of antibody heavy or light chains or mixtures thereof. Thus, monoclonal antibodies against an integrin molecule and fragment thereof are the preferred binding agent in the method of the invention.

As used herein, the term "antibody homolog" includes intact antibodies consisting 30 of immunoglobulin light and heavy chains linked via disulfide bonds. The term "antibody

homolog” is also intended to encompass a protein comprising one or more polypeptides selected from immunoglobulin light chains, immunoglobulin heavy chains and antigen-binding fragments thereof which are capable of binding to one or more antigens (i.e., $\alpha 1$, $\alpha 2$, $\alpha 6$ or alpha-I domain containing integrin subunits). The component polypeptides of an antibody homolog composed of more than one polypeptide may optionally be disulfide-bound or otherwise covalently crosslinked.

Accordingly, therefore, “antibody homologs” include intact immunoglobulins of types IgA, IgG, IgE, IgD, IgM (as well as subtypes thereof), wherein the light chains of the immunoglobulin may be of types kappa or lambda.

“Antibody homologs” also include portions of intact antibodies that retain antigen-binding specificity, for example, Fab fragments, Fab’ fragments, F(ab’)2 fragments, F(v) fragments, heavy chain monomers or dimers, light chain monomers or dimers, dimers consisting of one heavy and one light chain, and the like. Thus, antigen-binding fragments, as well as full-length dimeric or trimeric polypeptides derived from the above-described antibodies are themselves useful.

As used herein, a “humanized antibody homolog” is an antibody homolog, produced by recombinant DNA technology, in which some or all of the amino acids of a human immunoglobulin light or heavy chain that are not required for antigen binding have been substituted for the corresponding amino acids from a nonhuman mammalian immunoglobulin light or heavy chain.

As used herein, a “chimeric antibody homolog” is an antibody homolog, produced by recombinant DNA technology, in which all or part of the hinge and constant regions of an immunoglobulin light chain, heavy chain, or both, have been substituted for the corresponding regions from another immunoglobulin light chain or heavy chain. In another aspect the invention features a variant of a chimeric molecule which includes: (1) an integrin targeting moiety; (2) optionally, a second peptide, e.g., one which increases solubility or in vivo life time of the integrin targeting moiety, e.g., a member of the immunoglobulin super family or fragment or portion thereof, e.g., a portion or a fragment of IgG, e.g., the human IgG1 heavy chain constant region, e.g., CH2 and CH3 hinge regions; and a toxin moiety. The chimeric molecule can be used to treat a subject, e.g., a

human, at risk for disorder related to proliferation of epithelial cells such as hair follicles and the like.

As used herein, a "human antibody homolog" is an antibody homolog produced by recombinant DNA technology, in which all of the amino acids of an immunoglobulin light or heavy chain that are derived from a human source.

As used herein, "an inflammatory disorder", includes, but is not limited to, such disorders as, skin related conditions such as psoriasis, eczema, burns and dermatitis. Other inflammatory disorders contemplated for treatment by the methods of the present invention include but are not limited to the treatment of asthma, bronchitis, menstrual cramps, tendinitis, bursitis, and the treatment of pain and headaches, or as an antipyretic for the treatment of fever. The methods of the invention also would be useful to treat gastrointestinal conditions such as inflammatory bowel disease, Crohn's disease, gastritis, irritable bowel syndrome and ulcerative colitis and for the prevention of colorectal cancer. The methods of the invention would be useful in treating inflammatory disorders in such diseases as vascular diseases, migraine headaches, periarteritis nodosa, thyroiditis, aplastic anemia, Hodgkin's disease, rheumatic fever, type I diabetes, myasthenia gravis, multiple sclerosis, sarcoidosis, nephrotic syndrome, Behcet's syndrome, polymyositis, gingivitis, hypersensitivity, conjunctivitis, swelling occurring after injury, myocardial ischemia, and the like. The methods of the invention are also useful in the treatment of allergic rhinitis, respiratory distress syndrome, endotoxin shock syndrome, and atherosclerosis.

In a preferred embodiment, the methods of the invention are useful in the treatment of arthritis, including for example, rheumatoid arthritis and osteoarthritis.

An "effective amount" is an amount sufficient to effect beneficial or desired clinical results. An effective amount can be administered in one or more administrations. In terms of treatment of an inflammatory disorder, an "effective amount" of an anti-integrin antibody is an amount sufficient to palliate, ameliorate, stabilize, reverse, slow or delay progression of an inflammation-related condition in accordance with clinically acceptable standards for disorders to be treated or for cosmetic purposes. Detection and measurement of indicators of efficacy may be measured by a number of available diagnostic tools, including but not limited to, for example, by physical examination including blood tests,

pulmonary function tests, and chest X-rays; CT scan; bronchoscopy; bronchoalveolar lavage; lung biopsy and CT scan.

The technology for producing monoclonal antibodies, including for example, anti-integrin monoclonal antibodies is well known. See for example, Mendrick et al. 1995,

- 25 In general, an immortal cell line (typically myeloma cells) is fused to lymphocytes (typically splenocytes) from a mammal immunized with whole cells expressing a given antigen, e.g., an integrin, and the culture supernatants of the resulting hybridoma cells are screened for antibodies against the antigen. See, generally, Kohler et al., 1975, *Nature*

265: 295-497, "Continuous Cultures of Fused Cells Secreting Antibody of Predefined Specificity".

Immunization may be accomplished using standard procedures. The unit dose and immunization regimen depend on the species of mammal immunized, its immune status, the body weight of the mammal, etc. Typically, the immunized mammals are bled and the serum from each blood sample is assayed for particular antibodies using appropriate screening assays. For example, anti-integrin antibodies may be identified by immunoprecipitation of ¹²⁵I-labeled cell lysates from integrin-expressing cells.

Antibodies, including for example, anti-integrin antibodies, may also be identified by flow cytometry, e.g., by measuring fluorescent staining of antibody-expressing cells incubated with an antibody believed to recognize integrin molecules. The lymphocytes used in the production of hybridoma cells typically are isolated from immunized mammals whose sera have already tested positive for the presence of anti-integrin antibodies using such screening assays.

Typically, the immortal cell line (e.g., a myeloma cell line) is derived from the same mammalian species as the lymphocytes. Preferred immortal cell lines are mouse myeloma cell lines that are sensitive to culture medium containing hypoxanthine, aminopterin and thymidine ("HAT medium"). Typically, HAT-sensitive mouse myeloma cells are fused to mouse splenocytes using 1500 molecular weight polyethylene glycol ("PEG 1500"). Hybridoma cells resulting from the fusion are then selected using HAT medium, which kills unfused and unproductively fused myeloma cells (unfused splenocytes die after several days because they are not transformed). Hybridomas producing a desired antibody are detected by screening the hybridoma culture supernatants. For example, hybridomas prepared to produce anti-integrin antibodies may be screened by testing the hybridoma culture supernatant for secreted antibodies having the ability to bind to a recombinant integrin-expressing cell line.

To produce antibody homologs, including for example, anti-integrin antibody homologs, that are intact immunoglobulins, hybridoma cells that tested positive in such screening assays were cultured in a nutrient medium under conditions and for a time sufficient to allow the hybridoma cells to secrete the monoclonal antibodies into the culture

medium. Tissue culture techniques and culture media suitable for hybridoma cells are well known. The conditioned hybridoma culture supernatant may be collected and the anti-integrin antibodies optionally further purified by well-known methods.

Alternatively, the desired antibody may be produced by injecting the hybridoma
5 cells into the peritoneal cavity of an unimmunized mouse. The hybridoma cells proliferate in the peritoneal cavity, secreting the antibody which accumulates as ascites fluid. The antibody may be harvested by withdrawing the ascites fluid from the peritoneal cavity with a syringe.

Fully human monoclonal antibody homologs against, for example integrins, are
10 another preferred binding agent which may block antigens in the method of the invention. In their intact form these may be prepared using in vitro-primed human splenocytes, as described by Boerner et al., 1991, J. Immunol. 147:86-95, "Production of Antigen-specific Human Monoclonal Antibodies from *In Vitro*-Primed Human Splenocytes".

Alternatively, they may be prepared by repertoire cloning as described by Persson
15 et al., 1991, Proc. Nat. Acad. Sci. USA 88: 2432-2436, "Generation of diverse high-affinity human monoclonal antibodies by repertoire cloning" and Huang and Stollar, 1991, J. Immunol. Methods 141: 227-236, "Construction of representative immunoglobulin variable region CDNA libraries from human peripheral blood lymphocytes without *in vitro* stimulation". U.S. Patent 5,798,230 (Aug. 25, 1998, "Process for the preparation of
20 human monoclonal antibodies and their use") describes preparation of human monoclonal antibodies from human B cells. According to this process, human antibody-producing B cells are immortalized by infection with an Epstein-Barr virus, or a derivative thereof, that expresses Epstein-Barr virus nuclear antigen 2 (EBNA2). EBNA2 function, which is required for immortalization, is subsequently shut off, which results in an increase in
25 antibody production.

In yet another method for producing fully human antibodies, United States Patent
5,789,650 (Aug. 4, 1998, "Transgenic non-human animals for producing heterologous
antibodies") describes transgenic non-human animals capable of producing heterologous
antibodies and transgenic non-human animals having inactivated endogenous
30 immunoglobulin genes. Endogenous immunoglobulin genes are suppressed by antisense

polynucleotides and/or by antiserum directed against endogenous immunoglobulins.

Heterologous antibodies are encoded by immunoglobulin genes not normally found in the genome of that species of non-human animal. One or more transgenes containing sequences of unrearranged heterologous human immunoglobulin heavy chains are

5 introduced into a non-human animal thereby forming a transgenic animal capable of functionally rearranging transgenic immunoglobulin sequences and producing a repertoire of antibodies of various isotypes encoded by human immunoglobulin genes. Such heterologous human antibodies are produced in B-cells which are thereafter immortalized, e.g., by fusing with an immortalizing cell line such as a myeloma or by manipulating such
10 B-cells by other techniques to perpetuate a cell line capable of producing a monoclonal heterologous, fully human antibody homolog.

Yet another preferred binding agent which may block integrin antigens or fragments thereof in the method of the invention is a humanized antibody homolog having the capability of binding to an integrin protein or fragments thereof. Following the early
15 methods for the preparation of chimeric antibodies, a new approach was described in EP 0239400 (Winter et al.) whereby antibodies are altered by substitution of their complementarity determining regions (CDRs) for one species with those from another. This process may be used, for example, to substitute the CDRs from human heavy and light chain Ig variable region domains with alternative CDRs from murine variable region
20 domains. These altered Ig variable regions may subsequently be combined with human Ig constant regions to create antibodies which are totally human in composition except for the substituted murine CDRs. Such CDR-substituted antibodies would be predicted to be less likely to elicit an immune response in humans compared to chimeric antibodies because the CDR-substituted antibodies contain considerably less non-human components.
25 The process for humanizing monoclonal antibodies via CDR "grafting" has been termed "reshaping". (Riechmann et al., 1988 Nature 332: 323-327, "Reshaping human antibodies for therapy"; Verhoeyen et al., 1988, Science 239: 1534-1536, "Reshaping of human antibodies using CDR-grafting in Monoclonal Antibodies".

Typically, complementarity determining regions (CDRs) of a murine antibody are
30 transplanted onto the corresponding regions in a human antibody, since it is the CDRs

(three in antibody heavy chains, three in light chains) that are the regions of the mouse antibody which bind to a specific antigen. Transplantation of CDRs is achieved by genetic engineering whereby CDR DNA sequences are determined by cloning of murine heavy and light chain variable (V) region gene segments, and are then transferred to

5 corresponding human V regions by site directed mutagenesis. In the final stage of the process, human constant region gene segments of the desired isotype (usually gamma I for CH and kappa for CL) are added and the humanized heavy and light chain genes are co-expressed in mammalian cells to produce soluble humanized antibody.

The transfer of these CDRs to a human antibody confers on this antibody the
10 antigen binding properties of the original murine antibody. The six CDRs in the murine antibody are mounted structurally on a V region "framework" region. The reason that CDR-grafting is successful is that framework regions between mouse and human antibodies may have very similar 3-D structures with similar points of attachment for CDRs, such that CDRs can be interchanged. Such humanized antibody homologs may be
15 prepared, as exemplified in Jones et al., 1986 Nature 321: 522-525, "Replacing the complementarity-determining regions in a human antibody with those from a mouse"; Riechmann, 1988, Nature 332:323-327, "Reshaping human antibodies for therapy"; Queen et al., 1989, Proc. Nat. Acad. Sci. USA 86:10029, "A humanized antibody that binds to the interleukin 2 receptor" and Orlandi et al., 1989, Proc. Natl. Acad. Sci. USA 86:3833
20 "Cloning Immunoglobulin variable domains for expression by the polymerase chain reaction".

Nonetheless, certain amino acids within framework regions are thought to interact with CDRs and to influence overall antigen binding affinity. The direct transfer of CDRs from a murine antibody to produce a humanized antibody without any modifications of the
25 human V region frameworks often results in a partial or complete loss of binding affinity. In a number of cases, it appears to be critical to alter residues in the framework regions of the acceptor antibody in order to obtain binding activity.

Queen et al., 1989, Proc. Nat. Acad. Sci. USA 86: 10029-10033, "A
humanized antibody that binds to the interleukin 2 receptor" and WO 90/07861 (Protein
30 Design Labs Inc.) have described the preparation of a humanized antibody that contains

modified residues in the framework regions of the acceptor antibody by combining the CDRs of a murine mAb (anti-Tac) with human immunoglobulin framework and constant regions. They have demonstrated one solution to the problem of the loss of binding affinity that often results from direct CDR transfer without any modifications of the human V region framework residues; their solution involves two key steps. First, the human V framework regions are chosen by computer analysts for optimal protein sequence homology to the V region framework of the original murine antibody, in this case, the anti-Tac MAb. In the second step, the tertiary structure of the murine V region is modeled by computer in order to visualize framework amino acid residues which are likely to interact with the murine CDRs and these murine amino acid residues are then superimposed on the homologous human framework. Their approach of employing homologous human frameworks with putative murine contact residues resulted in humanized antibodies with similar binding affinities to the original murine antibody with respect to antibodies specific for the interleukin 2 receptor (Queen et al., 1989 [supra]) and also for antibodies specific for herpes simplex virus (HSV) (Co. et al., 1991, Proc. Nat. Acad. Sci. USA 88: 2869-2873, "Humanised antibodies for antiviral therapy").

According to the above described two step approach in WO 90/07861, Queen et al. outlined several criteria for designing humanized immunoglobulins. The first criterion is to use as the human acceptor the framework from a particular human immunoglobulin that is usually homologous to the non-human donor immunoglobulin to be humanized, or to use a consensus framework from many human antibodies. The second criterion is to use the donor amino acid rather than the acceptor if the human acceptor residue is unusual and the donor residue is typical for human sequences at a specific residue of the framework. The third criterion is to use the donor framework amino acid residue rather than the acceptor at positions immediately adjacent to the CDRS

One may use a different approach (see Tempest, 1991, Biotechnology 9: 266-271, "Reshaping a human monoclonal antibody to inhibit human respiratory syncytial virus infection *in vivo*") and utilize, as standard, the V region frameworks derived from NEWM and REI heavy and light chains respectively for CDR-grafting without radical introduction of mouse residues. An advantage of using the Tempest et al., 1991 approach to construct

NEWM and REI based humanized antibodies is that the 3dimensional structures of
NEWM and REI variable regions are known from x-ray crystallography and thus specific
interactions between CDRs and V region framework residues can be modeled.

The subject treatments are effective on both human and animal subjects afflicted
5 with these conditions. Animal subjects to which the invention is applicable extend to both
domestic animals and livestock, raised either as pets or for commercial purposes.
Examples are dogs, cats, cattle, horses, sheep, hogs and goats.

In the methods of the invention the antibodies, including for example, anti-VLA-1
antibody may be administered parenterally. The term "parenteral" as used herein includes
10 subcutaneous, intravenous, intramuscular, intra-articular, intra-synovial, intrasternal,
intrathecal, intrahepatic, intralesional and intracranial injection or infusion techniques.

The pharmaceutical compositions of this invention comprise any of the compounds
of the present invention, or pharmaceutically acceptable derivatives thereof, together with
any pharmaceutically acceptable carrier. The term "carrier" as used herein includes known
15 acceptable adjuvants and vehicles.

According to this invention, the pharmaceutical compositions may be in the form of
a sterile injectable preparation, for example a sterile injectable aqueous or oleaginous
suspension. This suspension may be formulated according to techniques known in the art
using suitable dispersing or wetting agents and suspending agents.

20 The pharmaceutical compositions of this invention may be given orally. If given
orally, they can be administered in any orally acceptable dosage form including, but not
limited to, capsules, tablets, aqueous suspensions or solutions.

For topical applications, the pharmaceutical compositions may be formulated in a
suitable ointment containing the active component suspended or dissolved in one or more
25 carriers.

The pharmaceutical compositions of this invention may also be administered by
nasal aerosol or inhalation through the use of a nebulizer, a dry powder inhaler or a
metered dose inhaler.

The dosage and dose rate of the compounds of this invention effective to produce
30 the desired effects will depend on a variety of factors, such as the nature of the inhibitor,

the size of the subject, the goal of the treatment, the nature of the pathology to be treated, the specific pharmaceutical composition used, and the judgment of the treating physician.

Dosage levels of between about 0.001 and about 100 mg/kg body weight per day, preferably between about 0.1 and about 50 mg/kg body weight per day of the active

ingredient compound are useful. Most preferably, the antibody homologs will be administered at a dose ranging between about 0.1 mg/kg body weight/day and about 20 mg/kg body weight/day, preferably ranging between about 0.1 mg/kg body weight/day and about 10 mg/kg body weight/day and at intervals of every 1-14 days. In another preferred embodiment the antibody is administered at a dose of about .3 to 1 mg/kg when administered I.P. In another preferred embodiment, the antibody is administered at a dose of about 5 to 12.5 mg/kg when administered I.V. Preferably, an antibody composition is administered in an amount effective to provide a plasma level of antibody of at least 1 ug/ml.

Persons having ordinary skill in the art can readily test if an antagonist of the invention is having its intended effect. For instance, cells contained in a sample of the individual's epithelium are probed for the presence of the agent in vitro (or ex vivo) using a second reagent to detect the administered agent. For example, this may be a fluorochrome labelled antibody specific for the administered agent which is then measured by standard FACS (fluorescence activated cell sorter) analysis. Alternatively, presence of the administered agent is detected in vitro (or ex vivo) by the inability or decreased ability of the individual's cells to bind the same agent which has been itself labelled (e.g., by a fluorochrome). The preferred dosage should produce detectable coating of the vast majority of hedgehog-positive cells. Preferably, coating is sustained in the case of an antibody homolog for a 1-14 day period.

Practice of the present invention will employ, unless indicated otherwise, conventional techniques of cell biology, cell culture, molecular biology, microbiology, recombinant DNA, protein chemistry, and immunology, which are within the skill of the art. Such techniques are described in the literature. See, for example, **Molecular Cloning: A Laboratory Manual**, 2nd edition. (Sambrook, Fritsch and Maniatis, eds.), Cold Spring Harbor Laboratory Press, 1989; **DNA Cloning**, Volumes I and II (D.N. Glover, ed), 1985;

- Oligonucleotide Synthesis**, (M.J. Gait, ed.), 1984; U.S. Patent No. 4,683,195 (Mullis et al.); **Nucleic Acid Hybridization** (B.D. Hames and S.J. Higgins, eds.), 1984; **Transcription and Translation** (B.D. Hames and S.J. Higgins, eds.), 1984; **Culture of Animal Cells** (R.I. Freshney, ed). Alan R. Liss, Inc., 1987; **Immobilized Cells and Enzymes**, IRL Press, 1986; **A Practical Guide to Molecular Cloning** (B. Perbal), 1984; **Methods in Enzymology**, Volumes 154 and 155 (Wu et al., eds), Academic Press, New York; **Gene Transfer Vectors for Mammalian Cells** (J.H. Miller and M.P. Calos, eds.), 1987, Cold Spring Harbor Laboratory; **Immunochemical Methods in Cell and Molecular Biology** (Mayer and Walker, eds.), Academic Press, London, 1987; **Handbook of Experiment Immunology**, Volumes I-IV (D.M. Weir and C.C. Blackwell, eds.), 1986; **Manipulating the Mouse Embryo**, Cold Spring Harbor Laboratory Press, 1986.

The following Examples are provided to illustrate the present invention, and should not be construed as limiting thereof.

EXAMPLES

15 Chemical reagents

Fluorescein isothiocyanate (FITC) was purchased from Sigma Chemical Co. (St. Louis, MO). Croton oil was purchased from ICN Biochemicals (Aurora, OH). Whole sheep blood in Alsevers solution was obtained from East Acres Biologicals (Southbridge, MA). Type I rat tail collagen and type IV mouse collagen were purchased from Collaborative Research Inc. (Bedford, MA) and Gibco (Gaithersburg, MD), respectively. Balb/c female mice of 6-8 weeks of age were purchased from Taconic (Germantown, NY) and the $\alpha 1\beta 1$ integrin-deficient mice on a Balb/c background were as previously described (3).

Example 1

25 *Monoclonal Antibodies.* Function-blocking mAbs to murine antigens were prepared in an azide-free and low endotoxin format: Ha31/8 (hamster anti-CD49a; integrin $\alpha 1$) (Mendrick et al. 1995. *Lab. Invest.* 72:367-375), Ha1/29 (hamster anti-CD49b; integrin $\alpha 2$) ($\beta 1$) (Mendrick et al. 1995. *Lab. Invest.* 72:367-375; Mendrick, D.L. and D.M. Kelly 1993 *Lab. Invest.* 69:690-702), hamster group II control mAb Ha4/8 (hamster anti-
30 KLH)(Mendrick, D.L. and D.M. Kelly 1993 *Lab. Invest.* 69:690-702), and PS/2 (rat anti-

CD49d; integrin $\alpha 4\beta 1$ chain) (Miyake et al. 1991 *J. Exp. Med.* 173:599-607). In addition, the following function-blocking mAbs to murine antigens were purchased as no-azide/low endotoxin preparations from Pharmingen (San Diego, CA): HM $\beta 1$ -1 (hamster anti-CD29; integrin $\beta 1$ chain) (Noto et al. 1995 *Int. Immunol.* 7:835-842), Ha2/5 (hamster anti-CD29; integrin $\beta 1$ chain) (Mendrick, D.L. and D.M. Kelly 1993 *Lab. Invest.* 69:690-702), 3E2 (hamster anti-CD54, ICAM-1) (Scheynius et al. 1993 *J. Immunol.* 150:655-663), 5H10-27 (rat anti-CD49e; integrin $\alpha 5$) (Kinashi, T., and T.A. Springer. 1994. *Blood Cells.* 20:25-44), GoH3 (rat anti-CD49f; integrin $\alpha 6$) (Sonnenberg et al. 1987 *J. Biol. Chem.* 262:10376-10383), and the rat isotype control mAbs R35-95 (rat IgG2a) and R35-38 (rat IgG2b).

Adhesion Assay. Splenocytes from Balb/c mice were cultured with 20 ng/ml IL-2 for 7-12 d. Adhesion of cells to type I and type IV collagen was as previously described (Gotwals et al. 1996 *J. Clin. Invest.* 97:2469-2477). Briefly, 96-well Maxisorp plates (Nunc, Napierville, IL) were coated with either 10 μ g/ml type IV or 5 μ g/ml type I collagen and non-specific sites blocked with 1% BSA. IL-2 activated splenocytes were labeled with 2 μ M BCECF [2',7'-bis(carboxyethyl)-5(6) carboxyl fluorescein penta acetoxymethylester] (Molecular Probes, Eugene, OR) and incubated with 10 μ g/ml of indicated mAbs for 15 min. 10^5 cells in 0.25% BSA in RPMI were then added to coated wells and incubated for 60 min at 37°C. Unbound cells were removed by washing three times with 0.25% BSA in RPMI. Adhesion was quantified using a CytoFluor 2350 fluorescent plate reader (Millipore, Bedford, MA). The ratio of bound cells to input cells was measured and percent adhesion relative to control mAb-treated cells (normalized to 100%) calculated. Background values due to cell adhesion on wells coated with BSA alone were subtracted.

Expression and functional blockade of $\alpha 1\beta 1$ and $\alpha 2\beta 1$ on activated leukocytes. Given the key role leukocytes play in inflammation, we decided to test whether anti- $\alpha 1$ and anti- $\alpha 2$ mAbs were capable of blocking leukocyte adhesion to collagens. In order to obtain leukocytes expressing high levels of both $\alpha 1$ and $\alpha 2$, murine T cells were stimulated *in vitro* with IL-2 for 7-12 d. These cells expressed high levels of both $\alpha 1$ and

$\alpha 2$ (Figure 1 A), and bound well to both collagen type IV and type I-coated surfaces (Figure 1 B). Adhesion to type IV collagen was partially inhibited by anti- $\alpha 1$ mAb alone and was not inhibited by anti- $\alpha 2$ mAb alone. In contrast, adhesion to type I collagen was completely inhibited by anti- $\alpha 2$ mAb and anti- $\alpha 1$ mAb alone showed only partial

5 inhibition. Both anti- $\beta 1$ mAb and the combination of anti- $\alpha 1$ and anti- $\alpha 2$ mAbs completely inhibited adhesion to types I and IV collagen. Having demonstrated that the $\alpha 1\beta 1$ and $\alpha 2\beta 1$ integrins are expressed on activated T cells and that anti- $\alpha 1$ and $\alpha 2$ mAbs are able to functionally block leukocyte adhesion to collagens, we used these mAbs to investigate the *in vivo* role of these integrins in animal models of inflammatory disorders.

10 Example 2

Inhibition of DTH responses by anti-integrin mAbs. SRBC-induced delayed type hypersensitivity (DTH) responses were adapted from a previously published protocol (Hurtrel et al. 1992 *Cell. Immunol.* 142:252-263). Briefly, mice were immunized s.c. in the back with 2×10^7 SRBC in 100 μ l PBS on d 0. The mice were challenged on d 5 by

15 injecting 1×10^8 SRBC in 25 μ l PBS s.c into the right hind footpad. Footpad thickness was measured with an engineer's caliper (Mitutoyo/MTI, Paramus, NJ) 20 h after antigen challenge, and the degree of footpad swelling calculated. Results are reported as the mean percent increase footpad thickness \pm SEM and calculated as % increase = [1- (Right footpad thickness 20 h after antigen challenge/Uninjected left footpad thickness 20 h after

20 antigen challenge)] x 100. To block the effector phase of the SRBC-induced DTH response, therapeutic or control mAb (100 μ g), which were prepared according to the methods described in Example 1, was given i.p. 1 h prior to antigen challenge on d 5.

SRBC-induced DTH is a well characterized *in vivo* model of inflammation, and in particular psoriasis, that has been used to demonstrate the importance of a variety of

25 cytokines and adhesion molecules in inflammation (Tedder et al. 1995 *J. Exp. Med.* 181:2259-2264, Terashita et al.1996 *J. Immunol.* 156:4638-4643). SRBC-sensitized mice received anti-integrin mAbs 1 h prior to footpad antigen challenge and inflammation was assessed 20 h later as measured by increased footpad thickness. PBS and control hamster Ig-treated mice showed a 60-70% increase in footpad thickness 20 h after antigen

30 challenge (Figure 2). Compared to control hamster Ig treatment, anti- $\alpha 1$ or anti- $\alpha 2$ mAbs

resulted in a 68% and 60% inhibition in footpad thickness, respectively. The combination of anti- α 1 and α 2 mAbs resulted in 71% inhibition, demonstrating little additive effect over anti- α 1 or anti- α 2 mAbs alone. Treatment with other anti-integrin mAbs was also effective at inhibiting DTH effector response. The degree of inhibition seen with the various mAb treatments was 49% (anti- α 4), 23% (anti- α 5), and 57% (anti- α 6). Lastly, mAb blockade of the common β 1 integrin subunit (mAb HMBI-1) inhibited the effector DTH response by 67%.

Example 3

Inhibition of CHS effector responses by anti-integrin mAbs. Contact

hypersensitivity (CHS) to FITC was assayed as previously described (Gaspari et al. 1991 *In Current Protocols in Immunology*. J.E. Coligan, A.M. Kruisbeek, D.H. Margulies, E.M. Shevach, and W. Strober, editors. John Wiley & Sons, New York. Section 4.2:1). Briefly, mice were sensitized by painting 100 μ l 0.5% FITC in 1:1 acetone/dibutylphthalate onto the shaved back on d 0. 10 d later, animals were challenged by applying 5 μ l 0.5% FITC onto both sides of each ear. Ear swelling response was determined by ear thickness measured with an engineer's caliper (Mitutoyo/MTI, Paramus, NJ) at the time of antigen challenge (d 10) and 24 h later, and the results reported as mean percent increase in baseline ear thickness \pm SEM. Increase in ear thickness was calculated as % increase = $[1 - (\text{Ear thickness 24 h after antigen challenge} / \text{Ear thickness at the time of antigen challenge})] \times 100$. To block the effector phase of the CHS response, therapeutic or control mAb (250 μ g) was given i.p. 4 h prior to antigen challenge on d 10. Mice that were antigen-sensitized and ear challenged with vehicle only (vehicle control) or mice that were ear challenged without prior sensitization (irritant control) served as negative controls (never exceeded 2% increase in ear thickness).

Given that CHS is mechanistically distinct from DTH and involves different effector cells, we investigated what effect anti-integrin mAbs had on the effector phase of the CHS response. Mice were hapten-sensitized using FITC applied to their shaved backs, followed 10 d later with FITC challenge to the ear resulting in an inflammatory response the next day. FITC-sensitized mice demonstrated a 60-70% increase in thickness 24 h after antigen challenge (Figure 3). Consistent with published results (Scheynius et al. J.

Immunol. 150:655-663), anti-ICAM-1 mAb treatment resulted in 51% inhibition of ear swelling. Compared to control hamster mAb, treatment of mice with anti- α 1 or anti- α 2 mAb 4 h prior to antigen challenge resulted in 37% and 57% inhibition in ear swelling, respectively (Figure 3). The combination of anti- α 1 and anti- α 2 mAbs resulted in slightly greater inhibition of ear swelling (65%). Treatment with other mAbs to β 1 integrins revealed that while anti- α 4 and anti- α 5 mAbs resulted in no inhibition of FITC-induced CHS effector response when compared to control rat mAb, treatment with anti- α 6 mAb resulted in an 86% inhibition of effector responses. Lastly, mAb blockade of the common β 1 integrin subunit inhibited CHS effector responses by 74%. Similar CHS results were obtained using different strains of mice (C57/BL6, 129/Sv) and a different sensitizing agent (oxazolone) (data not shown). Similar to the results seen in the SRBC-induced DTH model, histologic analysis of inflamed ears revealed that both edema formation and leukocytic infiltration were inhibited by anti- α 1 and anti- α 2 mAb treatment.

Consistent with the finding that α 1 β 1 and α 2 β 1 can be expressed on IL-2-activated splenocytes, analysis of lymph nodes from antigen-sensitized mice (FITC or oxazolone) revealed α 1 β 1 and α 2 β 1 to be expressed exclusively on CD44^{hi} LFA-1^{hi} activated CD4+ and CD8+ T cells (data not shown). Treatment of mice with anti- α 1 and anti- α 2 mAbs did not result in deletion of these cells, as the numbers of activated T cells in both spleen and lymph nodes seen in response to antigen sensitization in the CHS model was unaffected. In addition, effector cells were not functionally deleted as prolonged treatment of antigen-sensitized mice with anti- α 1 and anti- α 2 mAbs (d 10-16) did not affect the inflammatory response of mice challenged with antigen at d 20 (data not shown).

Example 4

CHS effector responses are decreased in α 1 β 1-deficient mice. To exclude the possibility that the inhibitory role of α 1 β 1 in the effector response of FITC-mediated CHS was mAb-mediated, experiments were carried out in wild-type and α 1 β 1-integrin deficient mice (Figure 4). MAb inhibition of the effector phase in wild-type mice was consistent with previous results, with 56% inhibition in ear thickness seen with anti- α 1, 56% with anti- α 2, and 62% with a combination of anti- α 1 and anti- α 2. The effector phase of CHS

was significantly reduced in untreated $\alpha 1\beta 1$ -deficient mice as compared to untreated wild-type mice (30% vs 71% increase in ear thickness, respectively). As expected, the level of ear swelling in untreated $\alpha 1\beta 1$ -deficient mice was equivalent to the level of ear swelling seen in anti- $\alpha 1$ mAb-treated wild-type mice. Lastly, mAb blockade of $\alpha 2\beta 1$ in the $\alpha 1\beta 1$ -deficient mice resulted in only slightly increased inhibition of ear swelling, consistent with the results seen in wild-type mice treated with a combination of anti- $\alpha 1$ and anti- $\alpha 2$ mAbs.

Example 5

To further exclude the possibility that the inhibitory effect of the anti-integrin mAbs seen in both the DTH and CHS models of inflammation is caused by a general anti-inflammatory effect mediated by the anti- $\alpha 1$ and anti- $\alpha 2$ mAbs, the effect of these mAbs on irritant dermatitis was studied.

To assess irritant dermatitis, mice were painted with 5 μ l of 0.8% croton oil in acetone on both sides of each ear. Therapeutic or control antibodies were given 4 h prior to the application of the irritant. Ear swelling was measured 24 h later as described above and compared to ear thickness prior to croton oil application. Results are reported as mean percent increase in baseline ear thickness \pm SEM as described above. Mice painted with acetone only (vehicle control) served as a negative control.

24 h later, ears of mice treated with croton oil showed a significant increase in ear thickness (48%), when compared to mice receiving vehicle only (acetone). Toxic ear swelling caused by croton oil was not significantly affected in mice pretreated with anti- $\alpha 1$ or anti- $\alpha 2$ mAbs when compared to either PBS or control mAb-treated animals (Figure 5). Histologic examination of the croton oil-treated ears revealed no differences in numbers or types of infiltrating cells or edema formation in mice treated with anti- $\alpha 1$ or anti- $\alpha 2$ mAbs, as compared to control mAb-treated mice or PBS-treated mice (data not shown).

Example 6

Inhibition of arthritis by $\alpha 1\beta 1$ and $\alpha 2\beta 1$. As $\alpha 1\beta 1$ is well expressed on infiltrating cells in the synovium of arthritis patients, we decided to examine whether anti- $\alpha 1$ or anti- $\alpha 2$ mAbs would be inhibitory in an accelerated model of arthritis previously described (Terato et al. 1992 *J. Immunol.* 148:2103-2108; Terato et al. 1995 *Autoimmunity* 22:137-147).

Arthrogen-CIA Antibody kits were purchased from Stratagene (La Jolla, CA) and arthritis induced using a well established protocol (Terato et al. 1992 *J. Immunol.* 148:2103-2108; Terato et al. 1995 *Autoimmunity.* 22:137-147). Briefly, arthritis was induced through i.p. injection of a cocktail of 4 anti-collagen type II mAbs (1 mg each) on d 0, followed by i.p. injection of 50 ug LPS on d 3. Over the course of the next 3-4 d, the mice developed swollen wrists, ankles and digits. Therapeutic or control mAb (250 ug) was administered i.p. 4 h prior to injection of the anti-collagen mAbs on d 0, and again 4 h prior to LPS administration on d 3, and then continuing every 3rd day for the length of the experiment. Beginning on d 3, mice were evaluated for the development of arthritis.

Severity of arthritis in each limb was scored using a four point system. 0=normal; 1=mild redness, slight swelling of ankle or wrist; 2=moderate swelling of ankle or wrist; 3=severe swelling including some digits, ankle, and foot; 4=maximally inflamed.

Severe arthritis in Balb/c mice developed within 72 h after LPS injection and persisted for more than 3 weeks. Neither injection of anti-collagen mAbs alone nor LPS alone induced arthritis. Mice receiving control mAb treatment displayed equally severe arthritis as than seen in PBS-treated mice (Figure 6). In contrast, treatment with anti- α 1 mAb alone resulted in a marked reduction (78%) in arthritis, lasting the duration of the experiment. Treatment with anti- α 2 mAb alone also had a beneficial effect, resulting in a 32% decrease in the arthritic score as compared to control mAb-treated mice. The combination of anti- α 1 and anti- α 2 mAbs resulted in a similar degree of inhibition as seen with anti- α 1 mAb alone.

Example 7

Histological analysis of effect of anti- α 1 and anti- α 2 mAb treatment on the inflammatory cellular infiltrate. Further histological analysis of the SRBC-induced DTH

response confirmed the ability of anti- α 1 and anti- α 2 mAb treatment to modulate the elicited inflammatory response (Figure 7). An unchallenged footpad from an SRBC-sensitized mouse (Figure 7 Panel A) showed virtually no inflammatory cellular infiltrate when compared to an SRBC-challenged footpad from the same mouse (Figure 7 Panel B).

Treatment of SRBC-sensitized mice with anti- α 1 and anti- α 2 mAbs either alone or combined greatly reduced the number of these infiltrating cells found in SRBC-challenged

footpads when compared to control mAb-treated mice (Figure 7 Panel C-F). Closer examination of the infiltrating cells revealed most cells to be composed of neutrophils, with some monocytes and lymphocytes present, and confirmed that anti- $\alpha 1$ and anti- $\alpha 2$ mAb treatment greatly decreased the numbers of these cells (Figure 7 Panel G-H).

5 **Example 8**

Immunohistochemical demonstration of $\alpha 1$ -expressing cells in the inflammatory cellular infiltrate. Immunohistochemistry was performed to more precisely determine the nature of the infiltrating cells and whether they express collagen-binding integrins (Figure 8). Infiltrating cells from an inflamed footpad of an untreated mouse were examined for
10 expression of $\alpha 1\beta 1$ integrin and cell lineage markers (Figure 8). $\alpha 1\beta 1$ integrin was found to be expressed on many infiltrating leukocytes (Figure 8 A). Dual immunohistochemistry was utilized to identify the nature of the infiltrating cells and the distribution of $\alpha 1\beta 1$ expression (Figure 8 B). Using cell lineage markers, the infiltrate was found to be composed largely of granulocyte/monocytes (Mac-1+), with many of these cells being
15 neutrophils (Gr1+), along with a smaller number of T lymphocytes (CD3+) (Figure 8 B). Expression of $\alpha 1\beta 1$ integrin was found among all three subsets of cells, with $\alpha 1$ expressed on a subset of Mac-1+ granulocyte/monocytes, a subset of Gr1+ neutrophils, and on the majority of infiltrating CD3+ T lymphocytes (Figure 8 B). Detailed immunohistochemical analysis revealed that although anti- $\alpha 1$ and anti- $\alpha 2$ mAb treatment reduced the numbers of
20 infiltrating cells, no change in the cellular composition of the infiltrate was seen (data not shown). Immunohistochemistry staining with a FITC anti-hamster mAb confirmed the ability of the anti- $\alpha 1$ and anti- $\alpha 2$ mAb to localize to the inflamed footpad (data not shown).

Example 9

25 *Inhibition of arthritis by mAbs to $\alpha 1\beta 1$ and $\alpha 2\beta 1$ and in $\alpha 1$ -deficient mice.* As $\alpha 1\beta 1$ is well expressed on infiltrating cells in the synovium of arthritis patients, we decided to examine whether anti- $\alpha 1$ or anti- $\alpha 2$ mAbs would be inhibitory in an accelerated model of arthritis previously described (Terato et al. 1992 *J. Immunol* 148:2103-2108; Terato et al. 1995 *Autoimmunity* 22:137-147). This model involves injection of a cocktail
30 of anti-collagen type II mAbs into mice, followed later by LPS administration, resulting in

the development of arthritis over the next 3-7 d. Mice were given mAb every 3rd day starting at d 0, and scored for the development of arthritis every 3rd day. Severe arthritis developed in all mice within 72 h after LPS injection and persisted for more than 3 weeks. Neither injection of anti-collagen mAbs alone nor LPS alone induced arthritis. Mice receiving control mAb treatment displayed equally severe arthritis as than seen in PBS-treated mice (Figure 9 A). In contrast, treatment with anti- α 1 mAb alone resulted in a marked reduction (79% and higher) in arthritis, lasting the duration of the experiment. Treatment with anti- α 2 mAb alone also had a beneficial effect, resulting in a 37% decrease in the arthritic score as compared to control mAb-treated mice. The combination of anti- α 1 and anti- α 2 mAbs resulted in a similar degree of inhibition as seen with anti- α 1 mAb alone. Reduction of arthritic score with anti- α 1 mAb treatment was seen in all mice and compares favorably with several other mAb-based treatments for arthritis such as soluble TNF receptor Ig fusion protein (Mori et al. 1996 *J. Immunol.* 157:3178-3182), anti-Mac-1 (Taylor et al. 1996 *Immunology.* 88:315-321), anti- α 4 (Seiffge 1996 *J. Rheumatol.* 23:2086-2091), and anti-ICAM-1 (Kakimoto et al. 1992 *Cell Immunol.* 142:326-337) (Figure 9A). In agreement with mAb-based data showing an important role for α 1 β 1 in arthritis, untreated α 1-deficient mice showed significant reduction in arthritic score when compared to wild-type mice (Figure 9 B).

Example 10

Effect of anti- α 1 mAb treatment on the immunopathology of arthritic joints. Joints from wild-type arthritic mice (day 8) receiving either control mAb or anti- α 1 mAb treatment were compared visually and histologically to joints from a normal untreated mouse (Figure 10). Visually, joints from control mAb-treated mice demonstrated redness and swelling of the entire foot including digits, while anti- α 1 mAb-treated mice showed little if any signs of inflammation in either joints or digits. Histologic examination showed severe changes in control mAb-treated arthritic joints, with extensive infiltration of the subsynovial tissue with inflammatory cells, adherence of cells to the joint surface, and marked cartilage destruction as evidenced by proteoglycan loss (Figure 10). Consistent with previous reports (Terato et al. 1992 *J. Immunol* 148:2103-2108; Terato et al. 1995 *Autoimmunity* 22:137-147), the majority of the infiltrating cells in this model are

neutrophils. Anti- $\alpha 1$ mAb treatment of mice dramatically reduced the amount of inflammatory infiltrate and the degree of cartilage destruction (Figure 10).

Example 11

Development of arthritis is delayed in the absence of lymphocytes and inhibition of arthritis by anti- $\alpha 1$ mAb occurs in the absence of lymphocytes. To determine what cell types might be important in the collagen mAb-induced arthritis model we compared the ability of wild-type B6-129 mice and RAG-1-deficient B6-129 mice to develop arthritis (Figure 11). Genetic deletion of the RAG-1 (recombination activating gene-1) gene results in a complete loss of mature T and B lymphocytes (Mombaerts et al. 1992 *Cell* 68:869-877). Both the wild-type and RAG-1-deficient mice developed arthritis, though the kinetics of induction in the RAG-1-deficient mice is significantly slower (Figure 11). These results suggest that while lymphocytes are involved in this model of arthritis, they are not required for the development and progression of the disease. Published reports examining the effect of the RAG-1-deficient mice in other models of arthritis also found that loss of T and B lymphocytes delayed the onset of arthritis (Plows et al. 1999 *J. Immunol.* 162:1018-1023). Treatment of either wild-type or RAG-1-deficient mice with anti- $\alpha 1$ mAb completely inhibited arthritis (Figure 11). These results demonstrate that the effectiveness of anti- $\alpha 1$ mAb in this model is not dependent on the presence of lymphocytes, and that as suggested by previous experiments (Figure 9), the efficacy of anti- $\alpha 1$ mAb in preventing disease may be through its action on other $\alpha 1$ -expressing cells, such as macrophages and neutrophils.

Example 12

Dose response of anti- $\alpha 1$ mAb inhibition of arthritis. Given the striking effects of anti- $\alpha 1$ mAb treatment on preventing arthritis, we extended these studies to include a dose response analysis (Figure 12). Different doses of mAb were administered i.p. every 3rd day starting at day 0. In agreement with earlier data, a 250 ug dose of anti- $\alpha 1$ mAb resulted in near complete prevention of arthritis. A lower dose of 100 ug of anti- $\alpha 1$ mAb was partially effective at preventing arthritis in this model, while lower doses did not have any discernable effect on arthritic score (Figure 12).

Example 13

Therapeutic treatment with anti- $\alpha 1$ mAb can decrease arthritic score. Given the effectiveness of anti- $\alpha 1$ mAb in preventing arthritis, we attempted to treat mice that are on their way to develop disease. Arthritis was induced in mice by injection of a cocktail of anti-collagen type II mAbs on day 0, followed by LPS administration on day 3. Mice were then treated with either anti- $\alpha 1$ mAb or a soluble TNF receptor Ig fusion protein starting on day 4. Progression of arthritis was completely blocked in mice receiving anti- $\alpha 1$ mAb starting at day 4, when compared to mice receiving control hamster mAb starting at day 4 (Figure 13). The degree of inhibition seen with therapeutic administration of anti- $\alpha 1$ mAb was complete and was equal to that seen with preventative treatment of anti- $\alpha 1$ mAb (started at day 0) (Figure 13). In comparison, treatment with TNF receptor Ig fusion protein from day 4 onwards resulted in only a 60-70% inhibition in arthritic score when compared to control Ig fusion protein (Figure 13). Combined treatment of anti- $\alpha 1$ mAb and TNF receptor Ig fusion together was effective at completely inhibiting arthritic score, which is not surprising given the complete effectiveness of anti- $\alpha 1$ mAb treatment alone in suppressing arthritis. In summary, these results indicate that therapeutic treatment with anti- $\alpha 1$ mAb is effective at inhibiting arthritic score, and compares favorably to therapeutic treatment with a TNF antagonist.

EXAMPLE 14

Cloning and mutagenesis of the $\alpha 1$ -I domain. Human and rat $\alpha 1\beta 1$ integrin I domain sequences were amplified from full length cDNAs (Kern, et al. (1994) *J. Biol. Chem.* **269**, 22811-22816; Ignatius et al. (1990) *J. Cell Biol.* **111**, 709-720) by the polymerase chain reaction (PCR) (PCR CORE Kit; Boehringer Mannheim, GmbH Germany), using either human specific (5'-CAGGATCCGTCAGCCCCACATTTCAA-3' [forward]; 5'-TCCTCGAGGGCTTGCAAGGCAAATAT-3' [reverse]) or rat specific (5'-CAGGATCCGTCAGTCCTACATTTCAA-3' [forward]; 5'-TCCTCGAGCGCTTCCAAAGCGAATAT-3' [reverse]) primers. The resulting PCR amplified products were purified, ligated into pGEX4t-i (Pharmacia), and transformed into competent DH5 α cells (Life Technologies). Ampicillin resistant colonies were screened for the expression of the ~45 kDa glutathione S-transferase-I domain fusion protein. The

sequences from inserts of plasmid DNA of clones that were selected for further characterization were confirmed by DNA sequencing.

A rat/human chimeric $\alpha 1$ -I domain (RAH) was generated (MORPH Mutagenesis kit; 5 prime – 3 prime), exchanging the rat residues G92, R93, Q94, and L97 (Figure 14) for the corresponding human residues, V, Q, R, and R, respectively. Clones harboring the RAH I domain were identified by the loss of a diagnostic Stu 1 restriction enzyme site, and the inserts confirmed by DNA sequencing. The amino acid sequence of the human $\alpha 1$ -I domain is shown in Figure 15.

Example 15

Generation of mAbs specific to the - $\alpha 1$ I domain. Monoclonal antibodies have proved to be very useful probes in studying the relationship between structure and function of integrin subunits. For example, mAbs were used extensively to study regions of the $\beta 1$ subunit associated with an activated conformation (Qu, A., and Leahy, D. J. (1996) *Structure* 4, 931-942). Thus, to identify potential probes for conformational changes of the $\alpha 1$ -I domain, we generated a panel of mAbs to the human $\alpha 1$ -I domain.

Generation of anti- $\alpha 1$ I domain Monoclonal Antibodies. Female Robertsonian mice (Jackson Labs) were immunized intraperitoneally (i.p.) with 25 μ g of purified human $\alpha 1\beta 1$ (Edwards et al. (1995) *J. Biol. Chem.* 270, 12635-12640) emulsified with complete Freund's adjuvant (LifeTechnologies). They were boosted three times i.p. with 25 μ g of $\alpha 1\beta 1$ emulsified with incomplete Freund's adjuvant (LifeTechnologies). The mouse with the highest anti- $\alpha 1$ -I domain titer was boosted i.p. with 100 μ g of $\alpha 1\beta 1$ three days prior to fusion, and intravenously with 50 μ g of $\alpha 1\beta 1$ one day prior to fusion. Spleen cells were fused with FL653 myeloma cells at a 1:6 ratio and were plated at 100,000 and 33,000 per well into 96 well tissue culture plates.

Supernatants were assessed for binding to the $\alpha 1\beta 1$ integrin by single color FACS. Prior to FACS analysis, supernatants were incubated with untransfected K562 cells to eliminate IgG that bound solely to the β subunit. Subsequently, $3-5 \times 10^4$ K562 cells transfected with the $\alpha 1$ integrin subunit (K562- $\alpha 1$) suspended in FACS buffer (1% fetal calf serum (FCS) in PBS containing 0.5% NaN₃) were incubated with supernatant for 45

minutes at 4° C, washed and incubated with anti-mouse IgG conjugated to phycoerythrin. After washing twice with FACS buffer, cells were analyzed in a Becton Dickinson Flow Cytometer.

Supernatants from the resulting hybridomas were screened for binding to the $\alpha 1$ -I domain. Briefly, 50 μ l of 30 μ g/ml human $\alpha 1$ -I domain-GST fusion in PBS was coated onto wells of a 96 -well plate (Nunc) overnight at 4° C. The plates were washed with PBS, blocked with 1% BSA in PBS and the hybridoma supernatant was incubated with the I domain at room temperature for 1 hour. After extensive washing with PBS containing 0.03% Tween 20, alkaline phosphatase linked anti-mouse IgG (Jackson ImmunoResearch) was added for an additional hour. After a final wash, 1 mg/ml *p*-nitrophenylphosphate (*p*NPP) in 0.1 M glycine, 1 mM ZnCl₂, and 1 mM MgCl₂ was added for 30 minutes at room temperature, and the plates were read at O.D. 405.

Selected supernatants were tested for their ability to inhibit K562- $\alpha 1$ dependent adhesion to Collagen IV. K562- $\alpha 1$ cells were labeled with 2 mM 2',7' (bis-2-carboxyethyl-5 and 6) carboxyfluorescein penta acetoxymethylester (BCECF; Molecular Probes) in DMEM containing 0.25% BSA at 37° C for 30 minutes. Labeled cells were washed with binding buffer (10 mM Hepes, pH 7.4; 0.9% NaCl; and 2% glucose) and resuspended in binding buffer plus 5 mM MgCl₂ at a final concentration of 1 X 10⁶ cells/ml. 50 μ l of supernatant was incubated with an equal volume of 2 X 10⁵ K562- $\alpha 1$ cells in wells of a 96 well plate. The plate was then centrifuged and the supernatants removed. Cells were resuspended in binding buffer and transferred to wells of a collagen-coated plate and incubated for 1 hour at 37° C. Following incubation, the non-adherent cells were removed by washing three times with binding buffer. Attached cells were analyzed on a Cytofluor (Millipore).

We initially identified 19 hybridomas, the supernatants of which bound to human leukemia K562 cells expressing the $\alpha 1\beta 1$ integrin (K562- $\alpha 1$) and to the $\alpha 1$ - I domain. The immunoglobulins were purified from each of these hybridomas and tested for the ability to block either K562- $\alpha 1$ or $\alpha 1$ - I domain binding to collagen IV. The mAbs fall into two classes: those that block and those that do not block $\alpha 1\beta 1$ function. For example, while the mAbs produced by clones AEF3, BGC5 and AJH10 bind the $\alpha 1$ -I domain

(Figure 16A, data not shown for BGC5), only mAb AJH10 inhibits α 1-I domain-dependent (Figure 16B) or K562- α 1 (Figure 16C) adhesion to collagen IV.

Sequencing of the Complementarity Determining Regions. To establish the clonal origin of this panel of mAbs, we amplified by PCR and sequenced the CDRs from 12 of the 19 antibodies (data not shown).

2 μ g of mRNA, isolated from 10^7 hybridomas (FastTrack mRNA isolation kit, Invitrogen), was reverse transcribed (Ready-To-Go You Prime First Strand Kit, Pharmacia Biotech) using 25 pM each of the following primers: heavy chain VH1FOR-2 (Michishita et al. (1993) *Cell* **72**, 857-867); light chain, VK4FOR, which defines four separate oligos (Kern et al. (1994) *J. Biol. Chem.* **269**, 22811-22816). For each hybridoma, heavy and light chains were amplified in four separate PCR reactions using various combination of the following oligos: 1) Heavy chain: VH1FR1K (Kamata et al. (1995) *J. of Biol. Chem.* **270**, 12531-12535), VH1BACK, VH1BACK (Baldwin et al. (1998) *Structure* **6**, 923-935), V_Hfr1a, V_Hfr1b, V_Hfr1e, V_Hfr1f, V_Hfr1g (Ignatius et al. (1990) *J. Cell Biol.* **111**, 709-720), or VH1FOR-2 (Michishita, M., Videm, V., and Arnaout, M. A. (1993) *Cell* **72**, 857-867); 2) Light chain: VK1BACK (Baldwin et al. (1998) *Structure* **6**, 923-935), VK4FOR, VK2BACK oligos (Kern et al. (1994) *J. Biol. Chem.* **269**, 22811-22816), or V_Kfr1a, V_Hfr1c, V_Hfr1e, V_Hfr1f (Ignatius et al. (1990) *J. Cell Biol.* **111**, 709-720). Products were amplified (5 min at 95° C, 50 cycles of 1 min at 94° C, 2 min at 55° C, 2 min at 72° C, and a final cycle of 10 min at 72° C), gel purified (QIAquick, Qiagen), and sequenced directly using various of the listed oligos on an ABI 377 Sequencer.

Sequences from clones producing function-blocking mAbs were nearly identical across all the complementarity-determining regions (CDRs) and the intervening framework regions suggesting that these hybridomas are clonally related.

Example 16

Immunoblotting and FACS Analysis. Sequences of the variable regions of the non-blocking antibodies were markedly different from the clonally related family of sequences found for the blocking antibodies. As the blocking antibodies appear to originate from a single clone, we chose one (AJH10) to characterize further.

Immunoblotting The smooth muscle cell layer dissected from sheep aorta, and K562- $\alpha 1$ cells were extracted with 1% Triton X-100 in 50 mM Hepes, pH 7.5, 150 mM NaCl, 10 mM phenylmethylsulfonyl flouride (PMSF), 20 μ g/ml aprotinin, 10 μ g/ml leupeptin, 10 mM ethylenediaminetetraacetic acid (EDTA). Samples were subjected to 4-20% gradient SDS-PAGE, and electroblotted onto nitrocellulose membranes. The blots were blocked with 5% dry milk in TBS; washed in TBS containing 0.03% Tween-20, and incubated with antibodies in blocking buffer containing 0.05% NaN_3 for 2 hours. Blots were then washed as before, incubated with horseradish peroxidase conjugated anti-mouse IgG for one hour, washed again and then treated with ECL reagent (Amersham). Blots were then exposed to film (Kodak) for 30 to 60 seconds, and developed.

Immunoblotting (Figure 17A) and FACS analysis (Figure 17B) demonstrate that AJH10 reacts with human, rabbit, and sheep, but not rat $\alpha 1\beta 1$ integrin suggesting that the blocking mAbs bind to an evolutionarily conserved, linear epitope. The non-blocking mAbs were neither efficient at immunoblotting nor did they react with species other than human.

Example 17

Binding of the $\alpha 1$ -I domain to collagen is divalent cation-dependent

A. Purification of the $\alpha 1$ -I domains.

The $\alpha 1$ -I domains were expressed in *E. coli* as GST (glutathione-S-transferase) fusion proteins containing a thrombin cleavage site at the junction of the sequences. The clarified supernatant from cells lysed in PBS was loaded onto a glutathione Sepharose 4B column (Pharmacia) which was washed extensively with PBS. The $\alpha 1$ -I domain-GST fusion protein was eluted with 50 mM Tris-HCl, pH 8.0, 5 mM glutathione (reduced). For denaturation studies, the I domain was cleaved with thrombin in 50 mM Tris, pH 7.5, and purified from the GST fusion partner. DTT was added to 2 mM and the sample was loaded on a glutathione Sepharose 4B column. The flow-through and wash fractions were pooled and loaded onto a Q Sepharose FF column (Pharmacia). The $\alpha 1$ -I domain was eluted with 50 mM Tris HCl, pH 7.5, 10 mM 2-mercaptoethanol, 75 mM NaCl. The purified I domain displayed its predicted mass (Lee et al. (1995) *Structure* **3**, 1333-1340, 871 Da) by electrospray ionization-mass spectrometry (ESI-MS), migrated as a single band

by SDS-PAGE, and the protein eluted as a single peak of appropriate size by size exclusion chromatography on a Superose 6 FPLC column (Pharmacia).

B. Functional Analysis

96 well plates were coated overnight at 4° C with 1 µg/ml collagen IV (Sigma) or collagen Type I (Collaborative Biomedical), washed with Triton buffer (0.1% Triton X-100; 1 mM MnCl₂; 25 mM Tris-HCl; 150 mM NaCl), and blocked with 3% bovine serum albumin (BSA) in 25 mM Tris-HCl; 150 mM NaCl (TBS). Serial dilutions of the α1- I domain-GST fusion protein in TBS containing 1 mM MnCl₂ and 3% BSA were incubated on the coated plates at room temperature for 1 hour, and washed in Triton buffer. Bound α1- I domain was detected with serial additions of 10 µg/ml biotinylated anti-GST polyclonal antibody (Pharmacia); ExtrAvidin-horseradish peroxidase (Sigma) diluted 1:3000 in TBS containing 1 mM MnCl₂ and 3% BSA, and 1-Step ABTS (2,2'-Azine-di[3-ethylbenzthiazoline sulfonate]; Pierce). Plates were read at O.D. 405 on a microplate reader (Molecular Devices).

Results.

The human and rat (95% identity to human) α1-I domains were expressed in *E. coli* as GST-fusion proteins and purified over glutathione sepharose. Both proteins were examined for binding to collagen I and IV using a variation of an ELISA-based assay previously described (Qu, A., and Leahy, D. J. (1995) *Proc. Natl. Acad. Sci. USA* **92**, 10277-10281). The human α1-I domain binds collagen IV with better efficiency than collagen I (Figure 18A). An antibody specific to the α1-I domain, but not an antibody specific to the α2-I domain (Figure 18B) abrogated binding to both ligands (data for collagen I is not shown). Both Mn²⁺ and Mg²⁺ stimulated binding, and EDTA reduced binding to background levels (Figure 18C). No measurable differences in ligand binding were detected between the human and rat α1-I domains suggesting that the sequence differences between species are not functionally relevant (data not shown). Thus, the α1-I domain, specifically, require cation for efficient ligand binding.

Example 18

A Cation-Dependent Epitope Resides near the MIDAS motif. We exploited the observation that AJH10 recognizes the human, but not the rat α1-I domain sequences to

map the epitope for the $\alpha 1\beta 1$ function-blocking mAbs. The human and rat sequences differ by only 12 amino acids, 4 of which lie in a stretch of 6 amino acids (aa 92-97, Figure 14A) adjacent to the critical threonine (Figure 14A, aa 98) within the MIDAS motif. To test the hypothesis that the 6 amino acid residues, Val-Gln-Arg-Gly-Gly-Arg, comprise the epitope for the blocking mAbs, we constructed a chimeric I domain (RAH), exchanging the rat residues G92, R93, Q94, and L97 for the corresponding human residues, V, Q, R, and R, respectively. AJH10, along with all the function-blocking mAbs, recognizes the chimeric I domain (RAH; Figure 14B).

To orient these residues with respect to the MIDAS domain in the tertiary structure of the $\alpha 1$ -I domain, we modeled the $\alpha 1$ -I domain using the coordinates of the crystal structure of the $\alpha 2$ I domain.

A homology model of the human $\alpha 1$ I-domain was built using the X-ray crystal structure of the human $\alpha 2$ I-domain (Ward et al. (1989) *Nature* **341**, 544-546). The model was built using the homology modeling module of Insight II (version 2.3.5; Biosym Technologies). The program CHARMM (Clackson et al. (1991) *Nature* **352**, 624-628) was used with the all-hydrogen parameter set 22 with a distant dependent dielectric constant of two times the atom separation distance. We first did 1000 steps of steepest descent minimization with mass-weighted harmonic positional constraints of 1kcal/(mol \AA^2) on all atoms of the $\alpha 1$ -I domain. This minimization was followed by another 1000 steps of steepest descent and 5000 steps of Adopted-Basis Newton Raphson with constraints of 0.1 kcal/(mol \AA^2) on the C- α atoms of the $\alpha 1$ -I domain to avoid significant deviations from the $\alpha 2$ -I domain X-ray crystal structure.

The $\alpha 1\beta 1$ and $\alpha 2\beta 1$ integrin sequences exhibit 51% identity with no insertions or deletions, suggesting that the overall structure of the two I domains will be similar. The metal coordination site is predicted to be the same in the $\alpha 1$ -I domain as in the $\alpha 2$ -I domain, and the residues that comprise the epitope for the blocking mAbs lie on a loop between helix $\alpha 3$ and helix $\alpha 4$ which contains the threonine within the MIDAS motif critical for cation binding. The $\alpha 1$ -I domain model predicts that the amide nitrogen of Q92 (Figure 14A) hydrogen bonds with the carbonyl group of I33, the residue adjacent to S32.

Thus, the loop that contains the epitope may play a functional role in stabilizing the MIDAS region.

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, it will be apparent to those skilled in the art that certain changes and modifications will be practiced. Therefore, the description and examples should not be construed as limiting the scope of the invention, which is delineated by the appended claims.
